

PLATE-FIN HEAT EXCHANGER

AH SERIES

Maximum dynamic pressure : 20 bar.

เพื่อป้องกันความเสียหายของแอร์คูลเลอร์ ต่อเชื้อควาส์หรือบายนพาสวาล์วทุกครั้ง

Calculation Of Air-Oil Heat Exchanger Installed On Hydraulic System

Introduction :

First of all, the choice of cooling system needs finding out the heat quantity of the hydraulic system, and furthermore we can design the appropriate cooling mode and ability for the requirements of clients.

The quantity of producing heat on hydraulic system cannot be estimate by calculation, because of the different of components and elements, using frequency and the design of circuit make this impossible.

1. Choosing the cooler rely on flow rate is only a basic condition, because we choice the input motor horse power by considering the pressure of pump and flow rate in the meantime.
2. The selecting of cooler depended on the quantity of producing heat matches up with the cooling capability on the system.
3. According to the actuality experience, we could count up the appraised value by inputting 70% electricity energy into the heat quantity.(Different engineer and elements make this different.)
4. If we using more delicate components and less heat quantity product, then the 70% heat quantity could be lower to 60% or much lower. Please confirm to your distributor.
5. If there is hydraulic motor in the circuit, then we should calculate the heat quantity up to 100%.

Data required

1.Simplify

Contrast the Input horse power with hydraulic horse power in the performance table, and you could find out the applicable cooler.

2.Calculate

N=installed power in the system (kW)

Q=heat to be dissipated (kcal/h)

T_o=maximum allowed oil temperature (°C)

T_{amb}=ambient temperature (°C)

K_r : Means the required specific performance of the heat exchanger

K_r= $Q/\Delta T$, dove ΔT is the difference between oil inlet temperature and summer ambient temperature, while Q is the quantity of heat to be dissipated which can be easily calculated considering 60-100% of installed power.

Example (hydraulic) :

$N = 20 \text{ kW}$ $T_o = 50^\circ\text{C}$ $T_{amb} = 35^\circ\text{C}$

$Q = 70\% \times 20 \text{ kW} = 14 \text{ kW} = 12040 \text{ kcal/h}$ ($1 \text{ kW} = 860 \text{ kcal/h}$)

$\Delta T = 50 - 35 = 15^\circ\text{C}$

$K_r = 12040 \text{ kcal/h} \div 15^\circ\text{C} = \underline{\underline{802 \text{ kcal/h}^\circ\text{C}}} = \underline{\underline{0.93 \text{ kw}^\circ\text{C}}}$

The choice of the correct cooler is made by using the diagrams.
You will find in our technical catalogues.

Equivalents among main units

1HP = 635kcal/h

1kW = 860 kcal/h

1 cSt = 1 mm²/ sec

1 BTU = 0.35 kcal/h

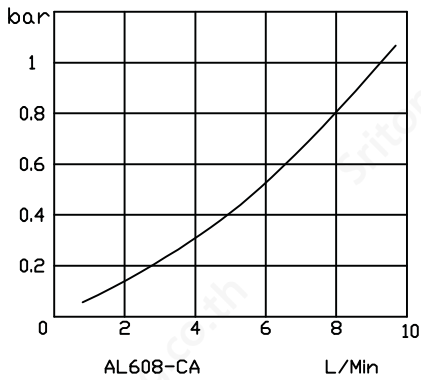

1 cSt = 1mm²/sec

1 bar = 100kpa
